<b>12</b>	<b>Conclusion</b>	<b>6</b>

# 1 Define the Goal

Before you even open the dataset, ask:

- What am I trying to achieve?
- Is this descriptive, diagnostic, predictive, or prescriptive?
- Who is the audience for this analysis?
- What decisions might rely on this?

**Example:** *“We want to understand what factors influence repeat purchases.”*  
Defining your goal gives direction. Without it, analysis becomes guesswork.

# 2 Understand the Dataset

Familiarize yourself with the structure and context of the data:

- What do the columns mean?
- What types of data are present? (Dates, numbers, text?)
- What does each row represent? A user? A transaction?
- Are there identifiers, timestamps, or calculated fields?

If a data dictionary is provided, use it. If not, build your own as you go.

# 3 Load and Review the Data

Once the data is opened, perform a structural check:

- Number of rows and columns
- Column names and types
- Formats and values (especially for dates, IDs)
- Initial red flags (e.g., nulls, duplicates, odd values)

This is like opening a puzzle box: count the pieces, check if any are missing or broken.

# 4 Explore the Data (EDA)

Exploratory Data Analysis (EDA) helps you become familiar with the dataset’s structure, quality, and potential stories.

## Key Goals of EDA:

- Understand distributions (normal, skewed, bimodal?)
- Identify potential outliers
- Examine variable relationships
- Assess data completeness and quality
- Generate initial hypotheses for future testing

## What You Should DO During EDA:

- **Profile numeric variables:** Calculate min, max, mean, median, standard deviation.
- **Profile categorical variables:** Count frequency and diversity of values.
- **Check for imbalance:** Are there categories that dominate?
- **Look for surprising values:** Negative prices? Ages above 120?
- **Compare variables:** Use cross-tabulations or group-by operations to identify interesting differences.
- **Note ideas:** EDA often sparks questions like, “Why do weekend purchases spike?” or “Why are men less likely to return?”

EDA is not about proving anything — it’s about becoming fluent in the shape of the data.

## 5 Clean the Data

Now that you’ve explored the data, clean it to make it usable:

- Handle missing values: drop or fill
- Convert incorrect types (e.g., strings to dates)
- Remove duplicates
- Standardize categorical entries (e.g., “M” and “Male”)
- Investigate and handle outliers where appropriate

Data cleaning is often the most time-consuming, but critical, step.

## 6 Feature Engineering

This step transforms raw data into valuable insight-generating variables.

- Extract date parts (year, month, weekday)
- Create flags or indicators
- Categorize continuous variables (e.g., age groups)
- Derive behavior-based metrics (e.g., days since last login)

Ask: What information would a business stakeholder find useful?

## 7 Visualize the Data

Turn findings into visuals to enhance both your understanding and communication.

### Goals of Visualization:

- Spot trends, anomalies, and relationships
- Compare groups or categories
- Display distributions clearly

### Common Charts and When to Use Them:

- **Bar Chart:** Compare categories
- **Line Chart:** Show change over time
- **Histogram:** Show distribution of a single variable
- **Box Plot:** Show spread and outliers
- **Scatter Plot:** Show relationships between variables

Visualization is a thinking tool, not just decoration.

## 8 Interpret Your Findings

At this stage, you're asking: what does all this *mean*?

- What behaviors or trends are consistent?
- What's surprising? What contradicts intuition?
- Are there important differences between groups?
- Can you tie data patterns to business behavior?

Turn observations into insights: *“Customers under 30 using promo codes are 35% more likely to return within 3 months.”*

Avoid over-interpreting. Stick to what the data shows.

## 9 Communicate the Results

Present your findings in a format that matches the audience:

### For Technical Audiences:

- Notebooks, code comments, reproducible steps

### For Business Stakeholders:

- Visual dashboards, executive summaries, recommendations

#### Tips:

- Use strong headlines (“Revenue dropped in Q3 due to seasonality”)
- Keep visuals clean and labeled
- End with 2–3 clear action points

## 10 Action Items

Once your analysis is complete, define next steps clearly:

- What decisions should be made based on your findings?
- Who should act on this? (Marketing, product, operations?)
- What follow-up analysis might be needed?
- Are there policies or systems that need updating?
- Should new metrics be monitored going forward?

**Insight without action is wasted.** Always translate your findings into steps someone can take.

## 11 Best Practices

- Start with the question, not the data
- Always keep a backup of the original dataset
- Document every cleaning and transformation step
- Be skeptical of outliers: understand them before removing

- Validate your assumptions, always
- Review your findings with someone else before sharing

## 12 Conclusion

Analyzing a dataset is not about running scripts – it’s about solving problems.

Each phase has its own logic:

- **Defining the goal** keeps you focused
- **Understanding the data** keeps you grounded
- **Cleaning the data** ensures accuracy
- **Engineering features** adds intelligence
- **Visualizing** adds clarity
- **Interpreting** adds meaning
- **Communicating** adds impact
- **Action items** turn insight into value

*”You’re not just analyzing data — you’re telling a story that drives decisions.”*
